Brown Clusters

The Brown Clustering Algorithm

- ► Input: a (large) corpus of words
- ▶ Output 1: a partition of words into *word clusters*
- Output 2 (generalization of 1): a hierarchichal word clustering

Example Clusters (from Brown et al, 1992)

Friday Monday Thursday Wednesday Tuesday Saturday Sunday weekends Sundays Saturdays June March July April January December October November September August people guys folks fellows CEOs chaps doubters commies unfortunates blokes down backwards ashore sideways southward northward overboard aloft downwards adrift water gas coal liquid acid sand carbon steam shale iron great big vast sudden mere sheer gigantic lifelong scant colossal man woman boy girl lawyer doctor guy farmer teacher citizen American Indian European Japanese German African Catholic Israeli Italian Arab pressure temperature permeability density porosity stress velocity viscosity gravity tension mother wife father son husband brother daughter sister boss uncle machine device controller processor CPU printer spindle subsystem compiler plotter John George James Bob Robert Paul William Jim David Mike anyone someone anybody somebody feet miles pounds degrees inches barrels tons acres meters bytes director chief professor commissioner commander treasurer founder superintendent dean custodian

A Sample Hierarchy (from Miller et al., NAACL 2004)

The Intuition

- Similar words appear in similar contexts
- More precisely: similar words have similar distributions of words to their immediate left and right

The Formulation

- $\triangleright \mathcal{V}$ is the set of all words seen in the corpus $w_1, w_2, \dots w_n$
- ▶ Say $C: \mathcal{V} \to \{1, 2, ... k\}$ is a *partition* of the vocabulary into k classes
- ► The model:

$$p(w_1, w_2, \dots w_n) = \prod_{i=1}^n e(w_i | C(w_i)) q(C(w_i) | C(w_{i-1}))$$

(note: $C(w_0)$ is a special start state)

$$p(w_1, w_2, \dots w_n) = \prod_{i=1}^n e(w_i | C(w_i)) q(C(w_i) | C(w_{i-1}))$$

$$p(w_1, w_2, \dots w_n) = \prod_{i=1}^n e(w_i | C(w_i)) q(C(w_i) | C(w_{i-1}))$$

$$C(\mathsf{the}) = 1, \quad C(\mathsf{dog}) = C(\mathsf{cat}) = 2, \quad C(\mathsf{saw}) = 3$$

$$p(w_1, w_2, \dots w_n) = \prod_{i=1}^n e(w_i | C(w_i)) q(C(w_i) | C(w_{i-1}))$$

$$C(\mathsf{the}) = 1, \quad C(\mathsf{dog}) = C(\mathsf{cat}) = 2, \quad C(\mathsf{saw}) = 3$$

$$e(\mathsf{the}|1) = 1, \quad e(\mathsf{cat}|2) = e(\mathsf{dog}|2) = 0.5, \quad e(\mathsf{saw}|3) = 1$$

$$p(w_1, w_2, \dots w_n) = \prod_{i=1}^n e(w_i | C(w_i)) q(C(w_i) | C(w_{i-1}))$$

$$C(\mathsf{the}) = 1, \quad C(\mathsf{dog}) = C(\mathsf{cat}) = 2, \quad C(\mathsf{saw}) = 3$$

$$e(\mathsf{the}|1) = 1, \quad e(\mathsf{cat}|2) = e(\mathsf{dog}|2) = 0.5, \quad e(\mathsf{saw}|3) = 1$$

$$q(1|0) = 0.2, \quad q(2|1) = 0.4, \quad q(3|2) = 0.3, \quad q(1|3) = 0.6$$

$$p(w_1, w_2, \dots w_n) = \prod_{i=1}^n e(w_i | C(w_i)) q(C(w_i) | C(w_{i-1}))$$

$$C(\mathsf{the}) = 1, \quad C(\mathsf{dog}) = C(\mathsf{cat}) = 2, \quad C(\mathsf{saw}) = 3$$

$$e(\mathsf{the}|1) = 1, \quad e(\mathsf{cat}|2) = e(\mathsf{dog}|2) = 0.5, \quad e(\mathsf{saw}|3) = 1$$

$$q(1|0) = 0.2, \quad q(2|1) = 0.4, \quad q(3|2) = 0.3, \quad q(1|3) = 0.6$$

p(the dog saw the cat) =

The Brown Clustering Model

A Brown clustering model consists of:

- ightharpoonup A vocabulary ${\cal V}$
- ▶ A function $C: \mathcal{V} \to \{1, 2, \dots k\}$ defining a *partition* of the vocabulary into k classes
- ▶ A parameter e(v|c) for every $v \in \mathcal{V}$, $c \in \{1 \dots k\}$
- ▶ A parameter q(c'|c) for every $c', c \in \{1 ... k\}$

Measuring the Quality of C

 \blacktriangleright How do we measure the quality of a partition C?

Quality(C) =
$$\sum_{i=1}^{n} \log e(w_i|C(w_i))q(C(w_i)|C(w_{i-1}))$$

 = $\sum_{c=1}^{k} \sum_{c'=1}^{k} p(c,c') \log \frac{p(c,c')}{p(c)p(c')} + G$

where G is a constant

Here

$$p(c,c') = \frac{n(c,c')}{\sum_{c,c'} n(c,c')}$$
 $p(c) = \frac{n(c)}{\sum_{c} n(c)}$

where n(c) is the number of times class c occurs in the corpus, n(c,c') is the number of times c' is seen following c, under the function C

A First Algorithm

- ightharpoonup We start with $|\mathcal{V}|$ clusters: each word gets its own cluster
- Our aim is to find k final clusters
- ▶ We run $|\mathcal{V}| k$ merge steps:
 - At each merge step we pick two clusters c_i and c_j , and merge them into a single cluster
 - We greedily pick merges such that

for the clustering C after the merge step is maximized at each stage

▶ Cost? Naive = $O(|\mathcal{V}|^5)$. Improved algorithm gives $O(|\mathcal{V}|^3)$: still two slow for realistic values of $|\mathcal{V}|$

A Second Algorithm

- ▶ Parameter of the approach is m (e.g., m = 1000)
- ightharpoonup Take the top m most frequent words, put each into its own cluster, $c_1, c_2, \ldots c_m$
- For $i = (m+1) \dots |\mathcal{V}|$
 - ightharpoonup Create a new cluster, c_{m+1} , for the i'th most frequent word. We now have m+1 clusters
 - ▶ Choose two clusters from $c_1 \dots c_{m+1}$ to be merged: pick the merge that gives a maximum value for Quality(C). We're now back to m clusters
- ightharpoonup Carry out (m-1) final merges, to create a full hierarchy

Running time: $O(|\mathcal{V}|m^2 + n)$ where n is corpus length

Name Tagging with Word Clusters and Discriminative Training

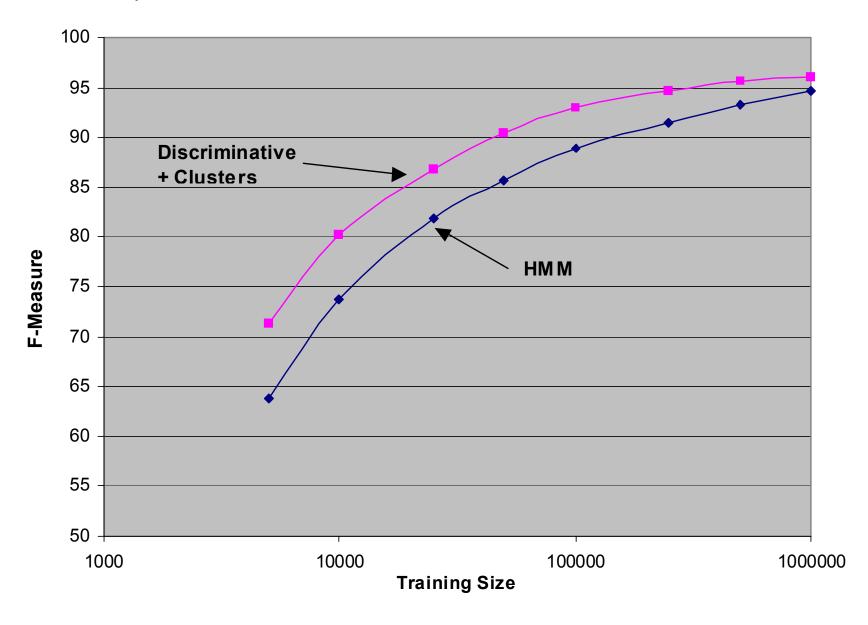

Scott Miller, Jethran Guinness, Alex Zamanian

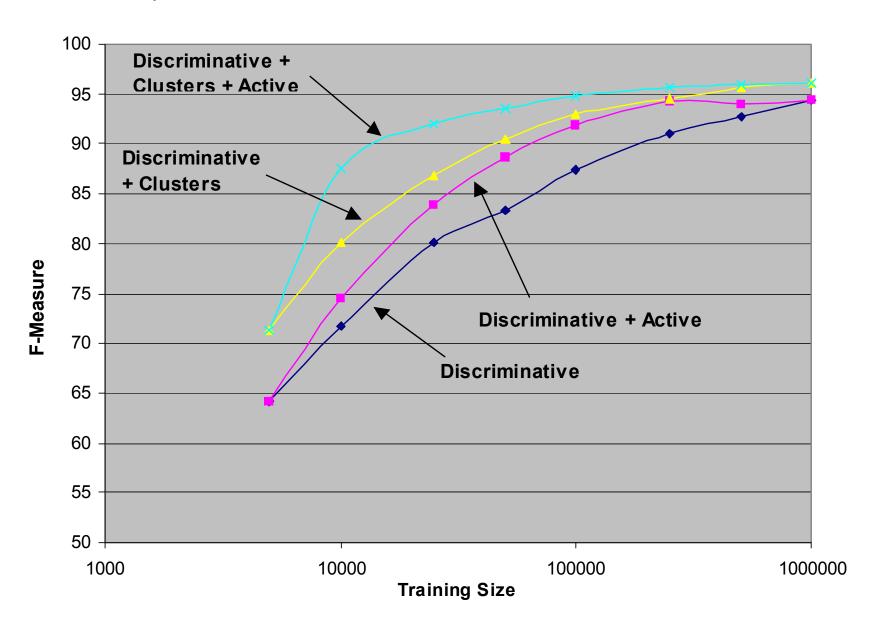

BBN Technologies 10 Moulton Street Cambridge, MA 02138 szmiller@bbn.com

At a recent meeting, we presented name-tagging technology to a potential user. The technology had performed well in formal evaluations, had been applied successfully by several research groups, and required only annotated training examples to configure for new name classes. Nevertheless, it did not meet the user's needs.

To achieve reasonable performance, the HMM-based technology we presented required roughly 150,000 words of annotated examples, and over a million words to achieve peak accuracy. Given a typical annotation rate of 5,000 words per hour, we estimated that setting up a name finder for a new problem would take four person days of annotation work – a period we considered reasonable. However, this user's problems were too dynamic for that much setup time. To be useful, the system would have to be trainable in minutes or hours, not days or weeks.

Owoputi et. al. NAACL 2013

Feature set	OCT27TEST	DAILY547	NPSCHATTEST	_
All features	91.60	92.80	91.19	1
with clusters; without tagdicts, namelists	91.15	92.38	90.66	2
without clusters; with tagdicts, namelists	89.81	90.81	90.00	3
only clusters (and transitions)	89.50	90.54	89.55	4
without clusters, tagdicts, namelists	86.86	88.30	88.26	5
Gimpel et al. (2011) version 0.2	88.89	89.17		6
Inter-annotator agreement (Gimpel et al., 2011)	92.2			7
Model trained on all OCT27		93.2		8

Table 2: Tagging accuracies (%) in ablation experiments. OCT27TEST and DAILY547 95% confidence intervals are roughly $\pm 0.7\%$. Our final tagger uses all features and also trains on OCT27TEST, achieving 93.2% on DAILY547.

Software for Brown Clusters
